Information

## Uninformed and cost-insensitive search

This quiz includes, among other things, two types of questions: tracing the frontier (in the generic graph search) for a given graph using DFS and BFS frontiers, and the implementation of these frontier classes in Python. You are expected to be able to do the tracing by hand, but you could also first write the frontier classes and make them generate the trace for you. Take the latter approach if you are fairly comfortable with doing the tracing by hand.

Information

## Optional activity: using the AI-Space search applet

AI-Space Group (<http://aispace.org>) provides a number of pedagogical tools in the area of AI. These tools are in the form of Java applets. One of these tools is a search applet which is available in the download section of the site. The search applet may be helpful in better understudying the graph search algorithms. The web site has some useful tutorials.

In most desktop environments (including the lab computers) you should be able to run the applet by double-clicking on the file. You can also run the program from a terminal, by typing the following command at the shell prompt:

```
java -jar path/to/search.jar
```

You will need Java Runtime Environment (JRE) in order to run this program. JRE is already installed on all the lab machines. At home, however, you may need to download it from <http://java.com> if it is not already installed on your system.

Question **1**

Correct

Mark 0.67 out of 1.00

Which of the following statements about a solution (a path to a goal node) found by depth-first search (DFS) is true?

Select one or more:

- ☒ a. The length (number of arcs) of the solution found by DFS depends on the order of children (edges) in the graph. 
- ☐ b. The algorithm always finds a solution with the lowest cost.
- ☐ c. The algorithm always finds the shallowest solution---a path with the fewest number of arcs.
- ☐ d. The algorithm always finds the deepest solution---a path with the largest number of arcs.

Correct

Marks for this submission: 1.00/1.00. Accounting for previous tries, this gives **0.67/1.00**.

## Frontier trace format

This information box appears in any quiz that includes questions on tracing the frontier of a graph search problem.

### Trace format

- Starting with an empty frontier we record all the calls to the frontier: to add or to get a path. We dedicate one line per call.
- When we ask the frontier to add a path, we start the line with a + followed by the path that is being added.
- When we ask for a path from the frontier, we start the line with a - followed by the path that is being removed.
- When using a priority queue, the path is followed by a comma and then the key (e.g. cost, heuristic, f-value, ...).
- The lines of the trace should match the following regular expression (case and space insensitive): `^[+-][a-z]+(,\d+)?!?$`
- The symbol ! is used at the end of a line to indicate a pruning operation. It must be used when the path that is being added to, or is removed from the frontier is to a node that is already expanded. Note that if a path that is removed from the frontier is pruned, it is not returned to the search algorithm; the frontier has to remove more paths until one can be returned.

### Precheck

You can check the format of your answer by clicking the "Precheck" button which checks the format of each line against a regular expression. Precheck only looks at the syntax of your answer and the frontier that must be used. It does not use the information in the graph object. So for example, + a would pass the format check for a BFS or DFS question even if the graph does not have a node called a.

If your answer fails the precheck, it will fail the check. If it passes the precheck, it may pass the main check, it may not. You will not lose or gain any marks by using "Precheck".

### Notes

- Frontier traces are not case sensitive - you don't have to type capital letters.
- There can be any number of white space characters between characters in a trace line and in between lines. When evaluating your answer, white spaces will be removed even if they are between characters.
- You can have comments in a trace. Comments start with a hash sign, #. They can take an entire line or just appear at the end of a line. Any character string appearing after # in a line will be ignored by the grader. You can use comments to keep track of things such as the visited set (when pruning).
- In questions where the search strategy is cost-sensitive (e.g. LCFS) you must include the cost information on all lines. The 'Precheck' button checks this for you.
- In questions where a priority queue is needed, the queue must be stable.

Question **2**  
Correct  
Mark 1.00 out of 1.00

Given the following graph, trace the frontier of a depth-first search (DFS).

```
ExplicitGraph(  
    nodes={'S', 'G'},  
    edge_list=[('S','G')],  
    starting_nodes = ['S'],  
    goal_nodes = {'G'},  
)
```

This question (and only this one) does not attract any penalty for wrong submissions. Please note the penalty regime in subsequent questions. Precheck is always free in all questions.

**Answer:** (penalty regime: 0 %)

Question **5**  
Correct  
Mark 0.67 out of 1.00

Which of the following statements about depth-first search is correct? In all the statements assume that the *generic search* algorithm is being used with a DFS frontier on a finite directed graph and that the frontier does not do pruning (i.e. it does not keep track of discovered/visited nodes).

Select one:

- ☐ The order of children (edges) does not have any effect on whether or not depth-first search halts.
- ☐ Depth-first search goes into an infinite loop on any finite directed graph that contains a cycle.
- ☒ If for a given graph, DFS halts with every possible edge ordering, then we can conclude that the order of edges does not have any effect on whether or not the algorithm finds a solution on that graph. ✓ If every edge ordering halts then either a solution is found every time or the graph is completely explored.
- ☐ The order of children (edges) does not have any effect on what solution is found by depth-first search.

Correct  
Marks for this submission: 1.00/1.00. Accounting for previous tries, this gives **0.67/1.00**.

Question **6**

Correct

Mark 1.00 out of 1.00

Given the following graph, trace the frontier of a breadth-first search (BFS).

```
ExplicitGraph(  
  nodes={'S', 'A', 'B', 'G'},  
  edge_list=[('A', 'B'), ('S', 'G'), ('S', 'A'), ('B', 'G')],  
  starting_nodes = ['S'],  
  goal_nodes = {'G'}  
)

Information

## Getting familiar with search.py

[search.py](#) is a small Python library that contains generic classes and functions related to graph search. The library is reasonably documented and clear. You need to download the file, and read and understand the library before you can proceed to answer the following programming questions.

We use Python generators quite often in this course. If you are not very familiar with them, read the documentation or find a tutorial online. For the impatient, the answers to [this question on the Stackoverflow](#) might be helpful.

## How your answer is tested on the server

Every time you submit a program to the server, the content of the answer box is written to a new file named "student\_answer.py". The test code then imports `student_answer` and other necessary modules and tests the functionality of the classes and functions by generating some output. A test passes if the generated output matches the expected output. This model entails the following points which you should keep in mind when working on similar programming questions:

1. You do **not** need to (and you shouldn't) copy the content of the search module into your file; only import it. The search module is available on the server.
2. Put your examples, test cases, or any other code that generates output in a separate function (for example `main`) so that when your answer is imported as a module by the test code, it does not print or do unwanted things and therefore does not affect the overall output of the test.
3. The idea of using a function like `main` is only for your convenience; it is not imported or used in the test cases. Therefore it does not matter whether or not you include it in the answer. If you include it, however, make sure the `main` function is not called by your module code and is not executed when the module is imported. For example use `if __name__ == "__main__": main()` when appropriate.
4. You must not have any global code that generates output.
5. If your code imports a module (for example imports the search module) then the code you paste in the answer box should also contain that import statement.
6. These points imply that if you follow a good coding practice, then you can simply paste the entire content of your program file in the answer box.

Question **8**

Correct

Mark 1.00 out of 1.00

## DFS Frontier

As it is mentioned in the documentation of the search module, you need to write a concrete subclass of Graph and a concrete subclass of Frontier in order to have a working graph search code. A concrete subclass of Graph called ExplicitGraph is already included in the search module. In this question, you have to write a concrete subclass of Frontier called DFSFrontier such that when an instance of it along with an instance of Graph are passed to the generic\_search function, the function behaves as a depth-first search algorithm.

► **Spoiler/Hint:** A Sample Incomplete Code (click here to expand)

For example:

Test	Result
<pre>from search import * from student_answer import DFSFrontier  graph = ExplicitGraph(nodes=set('SAG'),                       edge_list=[('S', 'A'), ('S', 'G'), ('A', 'G')],                       starting_nodes=['S'],                       goal_nodes={'G'})  solutions = generic_search(graph, DFSFrontier()) solution = next(solutions, None) print_actions(solution)</pre>	Actions: S->G. Total cost: 1
<pre>from search import * from student_answer import DFSFrontier  graph = ExplicitGraph(nodes=set('SAG'),                       edge_list=[('S', 'G'), ('S', 'A'), ('A', 'G')],                       starting_nodes=['S'],                       goal_nodes={'G'})  solutions = generic_search(graph, DFSFrontier()) solution = next(solutions, None) print_actions(solution)</pre>	Actions: S->A, A->G. Total cost: 2
<pre>from search import * from student_answer import DFSFrontier  available_flights = ExplicitGraph(     nodes=['Christchurch', 'Auckland',            'Wellington', 'Gold Coast'],     edge_list=[('Christchurch', 'Gold Coast'),                ('Christchurch', 'Auckland'),                ('Christchurch', 'Wellington'),                ('Wellington', 'Gold Coast'),                ('Wellington', 'Auckland'),                ('Auckland', 'Gold Coast')],     starting_nodes=['Christchurch'],     goal_nodes={'Gold Coast'})  my_itinerary = next(generic_search(available_flights, DFSFrontier()),                     None) print_actions(my_itinerary)</pre>	Actions: Christchurch->Wellington, Wellington->Auckland, Auckland->Gold Coast. Correct

Marks for this submission: 1.00/1.00.

Question **9**

Correct

Mark 1.00 out of 1.00

## BFS Frontier

Write a class `BFSFrontier` such that when an instance of it along with a graph object is passed to `generic_search`, breadth-first search (BFS) is performed.

It is strongly recommended that you use `collections.deque`. Also write `BFSFrontier` as a subclass of `Frontier` class (as opposed to writing it from scratch). This way you can make sure that your implementation has all the methods required by the abstract base class. You may even consider subclassing `DFSFrontier` if you think there are some functionalities in `DFSFrontier` that can be reused in the new class.

See the examples and make sure your submission includes all the class definitions that are imported by the test cases.

For example:

Test	Result
<pre>from search import * from student_answer import BFSFrontier  graph = ExplicitGraph(nodes=set('SAG'),                       edge_list = [('S','A'), ('S', 'G'), ('A', 'G')],                       starting_nodes = ['S'],                       goal_nodes = {'G'})  solutions = generic_search(graph, BFSFrontier()) solution = next(solutions, None) print_actions(solution)</pre>	Actions: S->G. Total cost: 1
<pre>from search import * from student_answer import BFSFrontier  flights = ExplicitGraph(nodes=['Christchurch', 'Auckland',                               'Wellington', 'Gold Coast'],                       edge_list = [('Christchurch', 'Gold Coast'),                                    ('Christchurch','Auckland'),                                    ('Christchurch','Wellington'),                                    ('Wellington', 'Gold Coast'),                                    ('Wellington', 'Auckland'),                                    ('Auckland', 'Gold Coast')],                       starting_nodes = ['Christchurch'],                       goal_nodes = {'Gold Coast'})  my_itinerary = next(generic_search(flights, BFSFrontier()), None) print_actions(my_itinerary)</pre>	Actions: Christchurch->Gold Coast. Total cost: 1

Question **10**

Correct

Mark 1.00 out of 1.00

Consider a state space graph with the following properties:

- Each state (node) is represented as an integer
- There is only a single starting state.
- For each state (number)  $n$ , two actions are available (in order): "1down" that goes to state  $n-1$  and "2up" which goes to state  $n+2$ .
- A state is considered a goal node if the number is divisible by 10.

Write a class `FunkyNumericGraph` as a subclass of `Graph` that implements the above description. The constructor should take one numeric argument which represent the single starting state. The cost of outgoing arcs must be set to 1 although the cost is not used during the search.

You can see that this is a graph with infinitely many states and edges which would never fit in the memory as an explicit graph. The given description, however, is enough to generate the graph on the fly as needed. Also the graph has infinitely many solutions. The object `solutions` in some test cases is an iterator. We use `next` to start/resume the algorithm and get the next solution.

**Important:** you must also provide the code for `BFSFrontier` from the previous question.

► **Spoiler/Hint:** A Sample Incomplete Code (click here to expand)

For example:

Test	Result
<pre>from student_answer import FunkyNumericGraph graph = FunkyNumericGraph(4) for node in graph.starting_nodes():     print(node)</pre>	4
<pre>from student_answer import FunkyNumericGraph graph = FunkyNumericGraph(4) for arc in graph.outgoing_arcs(7):     print(arc)</pre>	Arc(tail=7, head=6, action='1down', cost=1) Arc(tail=7, head=9, action='2up', cost=1)
<pre>from search import * from student_answer import FunkyNumericGraph, BFSFrontier  graph = FunkyNumericGraph(3) solutions = generic_search(graph, BFSFrontier()) print_actions(next(solutions)) print() print_actions(next(solutions))</pre>	Actions: 1down, 1down, 1down. Total cost: 3  Actions: 1down, 2up, 2up, 2up, 2up. Total cost: 5
<pre>from search import * from student_answer import FunkyNumericGraph, BFSFrontier from itertools import dropwhile  graph = FunkyNumericGraph(3) solutions = generic_search(graph, BFSFrontier()) print_actions(next(dropwhile(lambda path: path[-1].head &lt;= 10, solutions)))</pre>	Actions: 1down, 2up, 2up, 2up, 2up, 2up, 2up, 2up, 2up, 2up. Total cost: 10

**Answer:** (penalty regime: 0, 15, ... %)

Question **11**

Correct

Mark 1.00 out of 1.00

Sliding puzzles were discussed as an example in the lecture notes. Examples of this puzzle are the 8-puzzle and the [15-puzzle](#). The puzzle has an  $n$ -by- $n$  board. There are  $n^2-1$  square tiles on the board. The tiles are sequentially numbered starting from 1. The tiles can slide into an adjacent blank space. The objective of the game is to arrange the tiles in a way that the top-left corner is blank and then the numbers are ordered from left to right in each row and then from top to bottom.

Write a class `SlidingPuzzle` as a subclass of `Graph` that implements  $(n^2-1)$ -puzzles. States must be a list of  $n$  rows (lists) each having  $n$  elements. The first row (with index zero) is on the top. Complete the template provided in the answer box. You must also provide the code for `BFSFrontier`.

Note: since we assume that your search strategy (frontier class) is a simple BFS without more advanced features (e.g. pruning), the test cases only contain relatively small solvable puzzles. You will later see more advanced search strategies capable of solving more challenging instances of this problem.

For example:

Test	Result
<pre>from student_answer import SlidingPuzzleGraph, BFSFrontier from search import generic_search, print_actions  graph = SlidingPuzzleGraph([[1, 2, 5],                              [3, 4, 8],                              [6, 7, ' ']])  solutions = generic_search(graph, BFSFrontier()) print_actions(next(solutions))</pre>	Actions: Move 8 down, Move 5 down, Move 2 right, Move 1 right. Total cost: 4
<pre>from student_answer import SlidingPuzzleGraph, BFSFrontier from search import generic_search, print_actions  graph = SlidingPuzzleGraph([[3, ' '],                              [1, 2]])  solutions = generic_search(graph, BFSFrontier()) print_actions(next(solutions))</pre>	Actions: Move 3 right, Move 1 up, Move 2 left, Move 3 down, Move 1 right. Total cost: 5
<pre>from student_answer import SlidingPuzzleGraph, BFSFrontier from search import generic_search, print_actions  graph = SlidingPuzzleGraph([[1, ' ', 2],                              [6, 4, 3],                              [7, 8, 5]])  solutions = generic_search(graph, BFSFrontier()) print_actions(next(solutions))</pre>	Actions: Move 4 up, Move 3 left, Move 5 up, Move 8 right, Move 7 right, Move 6 down, Move 3 left, Move 4 down, Move 1 right. Total cost: 9

Answer: (penalty regime: 0, 15, ... %)
